Introduction to Multi-label Learning

Multi-label Learning

What is it?

- \rightarrow Multi-label learning is a form of classification where each instance may be associated with more than one label.
- ightarrow Text categorization fits naturally with multi-label learning

Why Use It?

- ightarrow Naive Approach: Train a sequence of independent binary classifiers (one per category)
- ightarrow Doesn't capitalize on the information in the correlations between the different labels of each instance.

Multi-label Paradigm: Definitions & Notation

- Let χ denote the domain of instances and $\mathcal{Y} = \{1, ..., Q\}$ be the finite set of labels.
- Given $x \in \chi$ and its associated $Y \subseteq \mathcal{Y}$, let \vec{y}_x be the category vector for x such that (for all $\ell \in \mathcal{Y}$) $\vec{y}_x(\ell) = 1$ if $\ell \in Y$. Otherwise, $\vec{y}_x(\ell) = 0$.

ML-KNN Approach

ML-KNN Algorithm: More Notation

Notation:

- Let N(x) denote the set of K nearest neighbors of x, identified in the training set.
- Let $\vec{C}_x(\ell) = \sum_{a \in N(x)} \vec{y}_a(\ell)$ ($\ell \in \mathcal{Y}$) define a membership counting vector.
- Let H_0^ℓ denote the event that test instance t does not have a label ℓ and let H_1^ℓ denote the event that it does have label ℓ .
- Let E_j^{ℓ} $(j \in \{1, ..., K\})$ denote the event that, among the K nearest neighbors of t, there are exactly j instances which have label ℓ .

ML-KNN Algorithm: Overall Approach

Overall Approach: This ML-KNN algorithm takes a parametric, Bayesian approach towards estimating the Bayes Optimal Classifier. As with the single-label algorithm, it does this using the K nearest neighbors of an instance. Namely...

• Given a test instance, t, \vec{Y}_t is determined using the MAP estimate:

$$\begin{split} \vec{y_t}(\ell) &= \underset{b \in \{0,1\}}{\operatorname{argmax}} \mathbb{P}\left(\mathbf{H}_b^{\ell} | E_{\vec{C_t}(\ell)}^{\ell}\right), \quad \ell \in \mathcal{Y} \\ &= \underset{b \in \{0,1\}}{\operatorname{argmax}} \frac{\mathbb{P}\left(\mathbf{H}_b^{\ell}\right) \cdot \mathbb{P}\left(E_{\vec{C_t}(\ell)}^{\ell} | \mathbf{H}_b^{\ell}\right)}{\mathbb{P}\left(E_{\vec{C_t}(\ell)}^{\ell}\right)} \\ &= \underset{b \in \{0,1\}}{\operatorname{argmax}} \mathbb{P}\left(\mathbf{H}_b^{\ell}\right) \cdot \mathbb{P}\left(E_{\vec{C_t}(\ell)}^{\ell} | \mathbf{H}_b^{\ell}\right) \end{split}$$

• Where we take a Bayesian approach towards estimating the prior probabilities, $\mathbb{P}\left(\mathbf{H}_b^\ell\right)$, and conditional probabilities, $\mathbb{P}\left(E_{\vec{c}_t(\ell)}^\ell|\mathbf{H}_b^\ell\right)$.

ML-KNN Algorithm: Overall Approach continued...

Definition: Let $\vec{\mathbf{r}}_t$ denote the real-valued vector with ℓ^{th} component:

$$\vec{\mathrm{r}}_t(\ell) := \mathbb{P}\left(\mathrm{H}_1^\ell\right)$$
.

 \Rightarrow Thus, given training data, \mathcal{X} , and a test instance, t, we wish to compute $[\vec{y}_t(\ell), \vec{r}_t(\ell)]$.

ML-KNN Algorithm: Computing the Prior Probabilities, $\widehat{\mathbb{P}(\mathrm{H}_{h}^{\ell})}$

We model $\mathbb{P}(H_1^{\ell})$ with a $\mathrm{Beta}(s,s)$ prior and $\mathrm{Bernoulli}(\mathbb{P}(H_1^{\ell}))$ likelihood. (When s=1, $\mathrm{Beta}(s,s)$ reduces to the uniform distribution on [0,1].)

 \Rightarrow The posterior distribution for $\mathbb{P}(\mathrm{H}_1^\ell)$ is:

$$\operatorname{Beta}\left(s+\sum_{i=1}^{m}\vec{y}_{x_{i}}(\ell),\ s+m-\sum_{i=1}^{m}\vec{y}_{x_{i}}(\ell)\right).$$

 \Rightarrow We will estimate $\mathbb{P}(\mathrm{H}_1^\ell)$ with the expectation of it's posterior Beta distribution:

$$\widehat{\mathbb{P}(\mathrm{H}_1^\ell)} \coloneqq \frac{s + \sum_{i=1}^m \vec{y}_{x_i}(\ell)}{2s + m}$$

where m is the number of training instances.

$$\Rightarrow$$
 We estimate $\widehat{\mathbb{P}(\mathrm{H}_0^\ell)}\coloneqq 1-\widehat{\mathbb{P}(\mathrm{H}_1^\ell)}.$

ML-KNN Algorithm: Computing the Conditional

Probabilities, $\mathbb{P}(\widehat{E_j^{\ell}|\mathrm{H}_b^{\ell}})$

Definition:

- (i) Let c be a vector of length K+1, where c(j)= the number of training instances where $\vec{C}_{x_i}(\ell)=j$ when $\vec{y}_{x_i}(\ell)=1$.
- (ii) Similarly, let c' be a vector of length K+1, where c(j)= the number of training instances where $\vec{C}_{x_i}(\ell)=j$ when $\vec{y}_{x_i}(\ell)=0$.

Model:

- * We give $\overrightarrow{\mathbb{P}(E_j^{\ell}|\mathrm{H}_1^{\ell})}$ (and $\overrightarrow{\mathbb{P}(E_j^{\ell}|\mathrm{H}_0^{\ell})}$) a $\mathrm{Dirichlet}(K+1,(s,...,s))$ prior distribution
- * We use a Categorical $(K+1,(\frac{c(0)}{m},...,\frac{c(K)}{m}))$ likelihood (analogously for $\mathbb{P}(E_i^{\ell}|\mathcal{H}_0^{\ell})$).
 - where $\overrightarrow{\mathbb{P}(E_j^\ell|\mathrm{H}_1^\ell)} = (\mathbb{P}(E_1^\ell|\mathrm{H}_1^\ell),...,\mathbb{P}(E_K^\ell|\mathrm{H}_1^\ell))$ (analogously for $\overline{\mathbb{P}(E_i^\ell|\mathrm{H}_0^\ell)}$).

ML-KNN Algorithm: Computing the Conditional Probabilities, $\widehat{\mathbb{P}(E_i^{\ell}|\mathcal{H}_b^{\ell})}$ continued...

 \Rightarrow The posterior distribution for $\overline{\mathbb{P}(E_j^\ell|H_1^\ell)}$ is

$$\operatorname{Dirichlet}\left(K+1,\left(s+c(0),...,s+c(K)\right)\right)$$

(and analogously for $\overrightarrow{\mathbb{P}(E_j^{\ell}|H_0^{\ell})}$.

 \Rightarrow Given $j \in \{1,...,K\}$, we estimate $\mathbb{P}(E_j^{\ell}|H_1^{\ell})$ and $\mathbb{P}(E_j^{\ell}|H_0^{\ell})$ with the expectations of their posterior distributions:

$$\mathbb{P}(\mathcal{E}_{j}^{\ell}|\mathcal{H}_{1}^{\ell}) := rac{(s+c(j))}{((K+1)s+\sum_{n=0}^{K}c(n))} \ \mathbb{P}(\mathcal{E}_{j}^{\ell}|\mathcal{H}_{0}^{\ell}) := rac{(s+c'(j))}{((K+1)s+\sum_{n=0}^{K}c'(n))}$$

Computing $\vec{y_t}$ and $\vec{r_t}$

Using our previous derivation:

$$\begin{split} \widehat{\vec{y_t}(\ell)} \coloneqq \operatorname*{argmax}_{b \in \{0,1\}} \left[\widehat{\mathbb{P}(H_b^{\ell})} \cdot \mathbb{P}(\widehat{E_{\vec{C}_{\mathcal{T}}(\ell)}^{\ell}} | H_b^{\ell}) \right] \\ \text{AND} \end{split}$$

$$\begin{split} \widehat{\vec{r_t}(\ell)} &:= \frac{\widehat{\mathbb{P}(H_1^{\ell})} \cdot \mathbb{P}(\widehat{E_{\vec{C}_{\mathcal{T}(\ell)}}^{\ell}}|H_1^{\ell})}{\sum_{b \in \{0,1\}} \left[\mathbb{P}(H_b^{\ell}) \cdot \mathbb{P}(E_{\vec{C}_t(\ell)}^{\ell}|H_b^{\ell}) \right]} \\ &= \frac{\widehat{\mathbb{P}(H_1^{\ell})} \cdot \mathbb{P}(\widehat{E_{\vec{C}_{\mathcal{T}(\ell)}}^{\ell}}|H_1^{\ell})}{\mathbb{P}(E_{\vec{C}_t(\ell)}^{\ell})} \end{split}$$

NOTE: The larger the value for s, the less importance assigned to the training data: As $s \to \infty$, $\vec{r_t}(\ell) \to \frac{1}{2}$.

Scikit-multilearn Implementation

Scikit-multilearn:

- The "scikit-learn" module is a free and widely used software machine learning library for Python, including many popular regression, classification and unsupervised learning algorithms.
- The "scikit-multilearn" module is a library for multi-label classification that is built on top of the scikit-learn ecosystem.

ML-KNN Classification in scikit-multilearn:

- → MLkNN() from the scikit-multilearn module can be used to instantiate a ML-KNN object.
- → "MLkNN" class methods like "fit()" and "predict()" mirror those for standard scikit-learn objects.

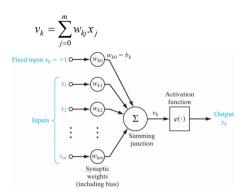

```
from skmultilearn.adapt import MLKNN
classifier = MLKNN(k=3)
# train
classifier.fit(X train, y train)
# predict
predictions = classifier.predict(X test)
```

BP-MLL Approach

Introduction to Feed-forward Networks: Perceptron Model

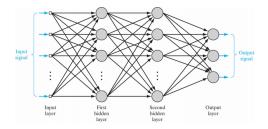

The perceptron model (and feed-forward networks, in general) can be viewed as a connected, directed, loop-free graph like the one below.

- Neurons in the first layer represent components of the input vectors
- The output of the neuron in the next layer is determined by applying a non-linear "activation function" to a linear combination of the input components, plus a bias.
- Rosenblatt's Perceptron model uses a step function non-linearity, but other common activation functions include the sigmoid function, $\sigma()$, tanh(), ReLU, Leaky ReLU, etc..

Multilayer Networks & Training

- Adding additional layers and units (like in the network pictured below) significantly expands the class of discrimination problems a network can learn.
- "Online" training involves evaluating an instance, and updating weights using gradient descent.
- For multi-label learning with Q instances, networks will have Q output layers, each with a tanh() activation.

Designing a Cost Function

As for standard networks, BP-MLL uses gradient descent & back propagation for learning. The novelty of the approach is in the design of the cost function.

Naive Approach ("BasicBP"):

Standard MSE:

$$E = \sum_{i=1}^{m} E_i = \sum_{i=1}^{m} \sum_{j=1}^{q} (c_j^i - d_j^i)^2$$

where $c_j^i = c_j(x_i)$ is the output of the network on x_i on the j^{th} class.

Novel Approach ("BP-MLL"):

BP-MLL Cost function:

$$E = \sum_{i=1}^{m} E_{i} = \sum_{i=1}^{m} \frac{1}{|Y_{i}||\overline{Y}_{i}|} \sum_{(k,l) \in Y_{i} \times \overline{Y}_{i}} \exp(-(c_{k}^{i} - c_{l}^{i}))$$

Back-propagation for training is derived just as in the standard (MSE) case (details omitted here, but can be found in Zhang and Zhou's paper).

Deep Learning APIs in Python: TensorFlow/Keras

<u>TensorFlow:</u> an open source python library for numerical computation and large-scale machine learning, created by the Google Brain team.

- ightarrow One of the most widely used APIs for deep learning, along with PyTorch and Keras.
- \rightarrow Later versions of TensorFlow began incorporating the Keras API, since users found its high-level design to be simpler.

```
import tensorflow as tf
mnist = tf.keras.datasets.mnist

(x_train, y_train),(x_test, y_test) = mnist.load_data()
x_train, x_test = x_train / 255.0, x_test / 255.0

model = tf.keras.models.Sequential([
    tf.keras.layers.Flatten(),
    tf.keras.layers.Dense(512, activation=tf.nn.relu),
    tf.keras.layers.Dense(10, activation=tf.nn.softmax)
])

model.compile(optimizer='adam',
    loss='sparse_categorical_crossentropy',
    metrics=['accuracy'])

model.fit(x_train, y_train, epochs=5)
model.evaluate(x_test, y_test)
```

TensorFlow Implementation of BP-MLL

BP-MLL in TensorFlow:

- → Data Scientist, Lukas Huwald, published an implementation of the bp-mll cost function for the TensorFlow API as part of the module "bpmll".
- ightarrow After installation, the bp-mll loss function can be utilized just as any other TensorFlow loss function.

```
# create simple mlp
model = Sequential()
model.add(Dense(128, input_dim=dim_no, activation='relu', kernel_initializer='glorot_uniform'))
model.add(Dense(64, activation='relu', kernel_initializer='glorot_uniform'))
model.add(Dense(class_no, activation='sigmoid', kernel_initializer='glorot_uniform'))
model.compile(loss=bp_mll_loss, optimizer='adagrad', metrics=[])
# train a few epochs
model.fit([X_train, Y_train, epochs=100])
```
